Types of Machine Banded Pipe

## PREFACE

This book contains miscellaneous hydraulic information, useful engineering tables and a complete table showing the Flow of Water in WOOD PIPES of various sizes and under varying heads. It is designed not only for the use of the Engineer, but is also intended for a handy reference book for the Mayor and his Council, the Water Superintendent, the Irrigator, the Miner, in fact for anyone who has occasion to divert water from its natural channel for the purpose of domestic uses, power plants, irrigation, etc.

As a means of conveying water for all purposes, whether the quantity be merely a few gallons a minute or hundreds of cubic feet per second, WOOD PIPE is now conceded by advanced engineers and experienced laymen to be an engineering and economic success.

The flow of water in WOOD PIPE is greater, size for size, than in pipe constructed of any other kind of material.

The flow tables herein given are based as far as possible on results obtained by various experiments and may be assumed to be as nearly correct as is required in a calculation of this kind.

We have endeavored to make the tables in this book in such simple form that they can be readily understood, and in order to assist in such an understanding, examples and explanations are given where necessary.

## PACIFIC TANK \& PIPE COMPANY.

## $2087 \% 6$

The Pacific Tank \& Pipe Company has factories and offices at

> Los Angeles, California,
> San Francisco, California,
> Portland, Oregon,

devoted exclusively to the manufacture and sale of

> FIR AND REDWOOD PIPE, FIR AND REDWOOD TANKS, STEAM PIPE CASING.

Machine Banded Pipe may be purchased f. o. b. cars at our factories or f. o. b. cars at point of destination. Services of an experienced pipe foreman will be furnished if desired.

Continuous Stave Pipe may be purchased in knocked down form, or we will contract to install the pipe in place.

While this book is especially devoted to WOOD PIPE and hydraulic data, we wish to call the attention of our patrons to the fact that TANKS may be purchased in knocked down form, f. o. b. cars our factories, or f. o. b. cars at point of destination. Services of an experienced tank erector will be furnished if desired, or we will contract for the erection of both tanks and tank towers.

If interested in TANKS, STEAM PIPE CASING or WOOD PIPE, write for descriptive matter.

When writing for prices on pipe, kindly observe as closely as possible the outline on the following page, and always address our nearest office.

## INFORMATION REQUIRED WITH INQUIRIES FOR MACHINE BANDED WOOD STAVE PIPE

1. The size or sizes of pipe you desire.
2. The length of each size.
3. Approximate head of each size, as follows:

Quantity Size Pipe | Head |
| :---: |
| Pressure |

| . | 25 feet |
| :---: | :---: |
| feet | 50 feet |
| feet | 75 feet |
| feet. | 100 feet |
| feet. | . 150 feet |
| feet. | . 200 feet |
| feet | . 250 feet |
| feet. | . 300 feet |
| .fe | 350 feet |
| .fee | 400 feet |

4. The quantity of water to be delivered.
5. Is your project to be a gravity, pumping or power system-what kind of pump or water wheel?
6. If possible send plans and profiles of system.
7. Name railway station at which freight is to be delivered.

## INFORMATION REQUIRED WITH INQUIRIES FOR CONTINUOUS WOOD STAVE PIPE

1. The size or sizes of pipe you desire.
2. The length of each size.
3. Approximate heads of each size in variations of ten feet, and lengths for each head.
4. The quantity of water to be delivered.
5. Is your project to be a gravity, pumping or power system-what kind of pump or water wheel?
6. If possible send plans and profiles of system.
7. Name railway station at which freight is to be delivered.

## TEN REASONS FOR USING WOOD PIPE

1. It is preserved by water and not rusted or corroded by it.
2. It is not corroded by sulphur, salt or mineral water and fumes.
3. It is not destroyed by acids or salts.
4. Its carrying capacity is $20 \%$ greater than cast iron pipe, and remains constant while metal pipe decreases with age.
5. It does not taint or affect fluids going through it.
6. It does not burst when frozen. The elasticity of the wood prevents bursting.
7. It requires less labor and experience to lay in place than metal pipe.
8. It can be laid in shallower ditches than metal pipe, for it is not easily affected by frosts.
9. It is cheaper than steel, wrought iron or cast iron pipe.
10. Its durability exceeds steel or wrought iron pipe, and is classed with cast iron pipe.

We manufacture Pipe and Tanks from both Douglas Fir and Redwood lumber, making a specialty of Fir at our Portland factory and Redwood at our San Francisco and Los Angeles factories.

## OUR SPECIALTIES

In addition to manufacturing wooden water pipe we are manufacturers of tanks for all purposes, and other specialties enumerated below.

Mining Tanks
Oil Tanks
Water Tanks
Wine Tanks
Solution Tanks
Leaching Tanks
Gold Storage Tanks
Vacuum Settling Tanks
Vacuum Clean-up Tanks
Vacuum Tanks
Sump Tanks
Chlorination Tanks
Rectangular Settling Tanks
Conical Bottom Settling Tanks
Pulp Thickener Tanks
Agitating Tanks
Wood and Iron Towers for Elevated Tanks

## COMPLETE CYANIDE PLANTS

If interested in mining or cyanide plant equipment, send for our mining catalog. This is fully illustrated and contains valuable information for the miner.

## "A WORD TO ENGINEERS"

In locating wood pipe lines for irrigation, power plants, city water systems, etc., there are several points that it would be well for the engineer to consider carefully.

First-Pipe designed for heavy pressure requires a greater amount of metal than low pressure pipe thereby increasing the cost; but, in running out a ditch line, it is frequently more economical to run across a valley, gulley or even a slight depression with an inverted syphon rather than follow the contour with a ditch.

Second-As has been shown by years of experience, the life of wood pipe is materially prolonged by the saturation of the staves, we, therefore, deem it good engineering practice, in all cases where conditions will permit, to drop the grade of the pipe as quickly as possible from the intake to a grade of 25 feet, or nearly, beneath the hydraulic grade line. This insures a pipe constantly full of water and the saturation of the top staves as well as the bottom, under pressure, while at the same time it does not affect the quantity of metal and therefore does not increase the cost.

Third-At all summits in the pipe line air valves, or vents, should be placed. These may consist of automatic devices, a number of which are on the market and have proven satisfactory; or, if the pipe location is on side hill, a pipe of sufficient diameter may be laid up the hill to an elevation slightly above the hydraulic grade line, or, where necessary, above the line of static pressure.

It is especially important that an air vent be placed at the point where the pipe drops with increased gradient to reservoir or power plant so that, in case more water be drawn off at the outlet than the light gradient above can supply, a vacuum will not be caused and collapse of the pipe will thus be averted.

Fourth-In determining the pressure head for which a wood pipe shall be banded, ample allowance should be made for water hammer or surge due to pumping or rapid closing of valves. The factor of safety should be based on the maximum
pressure to which the pipe can possibly be subjected. For example-a pumping line having a 45 -foot lift or static head, may have a friction head of 15 feet and a possible additional head of 20 feet due to water hammer. The pipe in this case should be banded for 80 -foot head.

Fifth-In drawing specifications remember that manufacturers have standard forms of construction that have been approved by engineers of ability and great experience. A deviation from standard means, usually, an increased cost and, most frequently, a product of inferior quality.

We procure for our pipe the best lumber that grows and is handled in the lumber market. The most carefully and rigidly drawn specifications cannot improve its quality.

The same is true of our other materials, steel rods, galvanized wire, cast iron, etc. They are manufactured of the best quality of raw material and are finished in the most suitable manner for the purpose for which they are intended.

As specifications on all materials are more or less subject to change we do not print them in this book, but for any specific project we will gladly furnish specifications upon request.

Sixth-While the PACIFIC TANK \& PIPE COMPANY is essentially a manufacturing organization, we do, however, in order to insure satisfaction to our customers, undertake to construct Continuous Stave Pipe in place or to lay Machine Banded Pipe in place under certain conditions, which are as follows:

The purchaser agrees to unload material from the cars, sort, haul and distribute the same along the line of the trench in the manner directed by us, do all trenching, backfilling, furnish and erect all trestles or structures other than pipe.

We furnish all material f. o. b. cars at point of delivery and construct the pipe in place under contract, or furnish the material as above and an experienced man to superintend the construction work at a price per diem.

PROFILE OF LINE FOR PUMPING PLANT

## DEFINITIONS

For illustration of definitions see cuts on opposite page.
The following definitions are not, on account of space, sufficiently comprehensive to satisfy the requirements of the practicing engineer. They will, however, be of interest to those who have neither the time nor the inclination to study, more deeply, the mysteries of hydraulics.

HEAD.-The word Head as applied to pipe lines has a variety of meanings and is sometimes carelessly used by engineers and laymen. The several meanings are classified and described in the following ways:

STATIC HEAD.-The Static Head is the difference in elevation between the surface of the water at the intake and the elevation of any given point in the pipe line. From this vertical measurement, which is usually stated in feet, is obtained the internal pressure per square inch which is hereinafter described under the title of Pressure.

TOTAL HEAD.-The Total Head (sometimes called Total Fall) is the difference in elevation between the water at the intake and the surface of the water at the outlet and, in connection with gravity lines with an open end discharge, is the sum of three items, viz.: Friction Head, Velocity Head and Entrance Head, which are defined in order.

FRICTION HEAD.-Assuming a gravity line discharging into a reservoir with the discharge end under the surface of the water, the Friction Head is the difference in elevation between the surface of the water at the intake and the elevation of the water at the outlet after the sum of the Velocity Head and the Entrance Head shall have been deducted. Should the discharge pipe be above the surface of the water then the center of the discharge end should be considered rather than the surface of the water in the reservoir.

Friction Head, also known as Loss due to Friction, is the difference in pressure (resolved into feet head) between any
two given points in a continuous line of pipe, the difference in pressure being due to the friction between the water and the interior surface of the pipe.

From the Friction Head is obtained the slope governing the flow of water in the pipe. This slope will be recognized under a definition given later as the Hydraulic Gradient.

VELOCITY HEAD.-The Velocity Head is a distance measured down from the surface of the water at the intake and is determined by the law of falling bodies. In order that the water in the pipe may flow with sufficient velocity to maintain the discharge for which it is designed a certain distance, or fall through space, must be utilized by the law of gravity in obtaining that velocity.

ENTRANCE HEAD.-The Entrance Head is generally assumed to be half of the Velocity Head and is due to the resistance caused by the eddies produced by the water entering the end of the pipe. This may be to a great extent overcome by using an enlarged or funnel shaped intake, but in most cases the velocity is not sufficiently great to make this item of moment. Especially is this true of long pipe lines where with a comparatively low velocity both the Entrance Head and the Velocity Head are so small that they can be omitted from consideration.

PRESSURE HEAD.-The Pressure Head is the difference in elevation between the surface of any confined body of water and any point in the container where it may be desired to ascertain the pressure. After the Pressure Head has been determined the pressure in pounds per square inch is obtained by multiplying the head in feet by .4335 . The pressure in pounds per square inch at any given point is equivalent to the actual weight of a column of water one inch square and equal in height to the Pressure Head.

PUMPING HEAD.-The Pumping Head is the sum of the Static Head and the Friction Head necessary to discharge the given quantity of water.

DYNAMIC HEAD.-The Dynamic Head, or Head or Fall
actually used in the production of power, is the difference in elevation between the point of discharge and the hydraulic gradient. In connection with turbine wheels the discharge point may be assumed to be the elevation of the tail water while in the case of tangential wheels the elevation of the center of the wheel should be considered.

In the design of a pipe line for a power system a certain amount of head is assumed to be lost, which is made up of the sum of the Friction Head, the Entrance Head and the Velocity Head. The remainder of the total head is the actual fall of water after all deductions have been made for the frictional and other losses and is the fall actually employed in producing power.

WORKING HEAD.-Working Head is a term frequently used and is generally misleading and therefore is not here defined.

HYDRAULIC GRADIENT OR HYDRAULIC GRADE LINE.- In the case of a pipe line having but one intake and one point of discharge, the Hydraulic Gradient is a theoretical line drawn from the surface of the water in the outlet to a point in the intake. This point is determined by measuring down from the surface of the water a distance corresponding to the sum of the Entrance Head and the Velocity Head. On the basis of the slope indicated by this line the velocity of the water is calculated.

The Hydraulic Gradient will be a broken line:
1.-If there be any change in the diameter of the pipe.
2.-If water be drawn off at a point or points other than the one point above mentioned.
3.-If any part of the pipe be constructed above a straight line drawn between the ends of the pipe.

[^0]SLOPE.-The Slope of the pipe line is obtained by dividing the Friction Head by the length of the pipe line. This result, in order to obtain the basis on which our table is calculated, must then be multiplied by 1000 .

COEFFICIENT OF FRICTION or COEFFICIENT OF ROUGHNESS.-The term Coefficient of Friction as used in formulae relating to the flow of water in pipes or channels is a factor indicating the resistance due to friction caused by roughness of the surface in contact with the flowing water.

Were the element of roughness entirely eliminated, the water would fall, by its own weight, according to the natural laws of gravity. The coefficients used in the Flow Tables given in this book have been selected as representing as nearly as possible the actual condition of friction encountered in wooden pipes. It is well to bear in mind that after service of a year or two, the interior of wooden pipe is much smoother than when new, the amount of friction is correspondingly less and as a consequence the velocity and discharge are greater. On the contrary, the flow of water in metal pipe never is as great as in wooden pipe and after short service the metal pipe tuberculates and corrodes to such an extent as to greatly increase the friction and diminish the discharge.

MEAN RADIUS OR HYDRAULIC RADIUS.-The Mean (or Hydraulic) Radius is the quotient, in feet, obtained by dividing the area of wet cross-section in square feet, by the wet perimeter in feet. In pipes running full or exactly half full, and in semi-circular open channels running full, it is equal to one-fourth of the inner diameter.

WET PERIMETER.-The Wet Perimeter is the sum of the lengths, in feet, found by measuring across the channel, such parts of its sides and bottom as are in contact with the water.

EXAMPLE.-A channel 3 feet deep by 6 feet wide with water running 2 feet 6 inches deep, has a Wet Perimeter equal to 2 feet 6 inches plus 2 feet 6 inches plus 6 feet 0 inches $=11$ feet.

The area of wet cross-section is $21 / 2 \times 6=15$ square feet.

## TABLE OF SPECIFIC GRAVITIES

$$
s=1 / 2(a+b+c)
$$

## CIRCLES

Circumference equals diameter $\times 3.1416$ or about 3 1-7.
The side of a square equal in area to a given circle equals diameter $\mathbf{x} 0.8862$.

The side of an inscribed square equals diameter $\times 0.7071$.
The diameter of a circle equals the circumference divided by 3.1416 .

The area of a circle equals the square of the diameter $\times 0.7854$ or the square of the radius $\times 3.1416$.

Lengths of arcs:

$$
\begin{aligned}
& \text { For } 1 \text { degree }=\text { Radius } \times .01745329 \text { Log. }=8.2418774 . \\
& \text { For } 1 \text { minute }=\text { Radius } \times .00029089 \text { Log. }=6.4637261 . \\
& \text { For } 1 \text { second }=\text { Radius } \times .000004848 \text { Log. }=4.6855749 .
\end{aligned}
$$

Volume of a sphere $=4.188 \times$ the cube of the radius, or $0.01689 \times$ the cube of the circumference.

Area of surface of sphere:
Equals $3.1416 \times$ the square of the diameter.
Equals $0.3183 \times$ the square of the circumference.
Equals the diameter x the circumference.

## EXAMPLES

1. How many cubic feet of water per second will have to be discharged in order to give 35 million gallons in 24 hours?

Gals. in 24 hrs. Cu. Ft. per Sec.

$$
\begin{aligned}
30,000,000 & =46.42 \\
\frac{5,000,000}{35,000,000} & =7.736 \\
54.156 & \text { Cu. Ft. per Sec. Ans. }
\end{aligned}
$$

2. How many cubic feet of water per second will have to be discharged in order to give $72,560,000$ gallons in eight hours?

Gals. in 8 hrs. Cu. Ft. per Sec.

$$
\begin{aligned}
70,000,000 & =324.92 \\
2,00,000 & =9.283 \\
500,000 & =2.3208 \\
60,000 & =\frac{.2785}{3} \\
\hline 72,560,000 & =336.8023 \text { Cu. Ft. per Sec. Ans. }
\end{aligned}
$$

## EXAMPLE

How many cubic feet per second will give 425,800 cubic feet in six hours flow?

| Cu. Ft. in <br> 6 hours. | Cu. Ft. <br> per sec. |
| ---: | :--- |
| 400,000 | $=18.52$ |
| 20,000 | $=$ |
| 5,000 | $=$ |
| 800 | $=\frac{.231}{}$ |
| 425,800 | $=$ |
| 19.714 | Cu. Ft. per Sec. Ans. |

Write for our Illustrated Tank Catalog.

## HYDRAULIC DATA

Gallons per day ( 24 hours) multiplied by .000001547 equals Cubic Feet per Second.

Cubic Feet per Second divided by .000001547 equals Gallons per day ( 24 hours).

A Cubic Foot of Water contains nearly $71 / 2$ gallons (7.48052) and weighs about $621 / 2$ pounds.

A Gallon of Fresh Water weighs 8.34 pounds and contains 231 cubic inches.

27154 Gallons of Water (3630 Cubic Feet) will cover one acre one inch deep.

The Miner's Inch has varying actual values in different states as follows:

One Second Foot equals 50 Miner's Inches in Utah, Idaho and Nevada.

One Second Foot equals 40 Miner's Inches in Montana and Arizona.

One Second Foot equals 38.4 Miner's Inches in Colorado.
Note. -The Miner's Inch given in the Flow Table in this book, is that generally spoken of as the California Inch, or $1 / 50$ of one second foot, which is customarily used by miners in that State. The California statute, however, provides that the Miner's Inch shall equal $11 / 2$ cubic feet per minute, or one second foot equals 40 Miner's Inches.

One Acre Foot equals 43560 Cubic Feet $=$ one second foot of water flowing for 12 hours and 6 minutes.

Doubling the diameter of a pipe multiplies its end area four times.

Theoretically water can be raised by suction 33 feet, but practically only 25 to 28 feet.

The amount of power developed by water flowing through a pipe may be ascertained by the following formula:

$$
\text { Horse Power }=.1134 \mathrm{HS}
$$

in which H equals the dynamic head in feet;
$S$ equals the cubic feet of water per second.
This gives a strictly theoretical result and from it must be deducted from $20 \%$ to $30 \%$ to cover machinc inefficiency.

Example. 50 second feet of water with 75 foot head: 75 times 50 times $.1134=425$. Deducting $20 \%$ for inefficiency will give 340 Horse Power.

| 19 | 33.12 | 33.45 | 33.78 | 34.11 | 34.44 | 34.77 | 35.10 | 35.44 |
| 20 | 35.77 | 36.11 | 36.45 | 36.78 | 37.12 | 37.46 | 37.80 | 38.15 |

Example Showing the Application of the above Table.
Suppose the Weir to be 60 inches long, and the depth of water on it to be $51 / 2$ inches. Follow down the left-hand column of the figures in the table until you come to 5 inches. Then run across the table on a line with the 5 , until under $1 / 2$ on top line, and you will find 5.15 . This multiplied by 60 , the length of Weir, gives 309 , the number of cubic feet of water passing per minute, and this multiplied by $71 / 2$ will give the gallons- $23171 / 2$.

To find the capacity of tanks greater than the largest given in the table, look in the table for a tank of one-half of the given size, and multiply its capacity by 4 , or one of onethird its size, and multiply its capacity by 9 , etc.

RULE.-Find the Mean Radius of the channel or flume by the metbod described under definitions of Mean Radius and Wet Perimeter.

Take from the table of velocities the number opposite the Mean Radius and under the suitable coefficient of roughness. This number must te multiplied by the multiple opposite the fall in the table of slopes. The result is the velocity in feet per second.

The quantity of water discharged is found by multiplying the area of the wet cross-section by the velocity.

## EXAMPLE

A box flume has four foot straight sides and an inside width of five feet, the water being calculated to run 3.75 feet deep with a fall of $11 / 2$ inches per 100 feet.

The wet perimeter is found to be 3.75 plus 3.75 plus $5=12.5$ feet.
The area of the wet cross-section is $3.75 \times 5=18.75$ square feet.
The Mean Radius is therefor $18.75 \div 12.5=1.5$.
Assuming that the coefficient in this case is . 015 , we refer to the table of velocities and under .015 and opposite 1.5 we find 13.11. Now refer to the table of slopes and opposite $11 / 2^{\prime \prime}$ we find the multiple .346. Multiplying 13.11 by .346 we obtain 4.54, which equals the velocity in feet per second of the water in the flume. The quantity of water carried by the flume is found to be $18.75 \times 4.54=$ 85.1 cubic feet per second.

Continuous Stave Pipe Used as an Irrigation Syphon

## TABLES FOR FLOW OF WATER THROUGH WOOD PIPE

In preparing the following tables for the flow of water through wooden pipes, such as are manufactured by us, we have given full consideration to all of the few tests that have been made from which intelligent deductions can be drawn. Unfortunately, most of the tests that have been made were with pipe constructed under unusual conditions or with greatly varying grades or curvature. It is our intention to show in these tables as nearly as possible the actual amount of water that will flow through wooden pipes with a minimum amount of curvature either vertical or horizontal. Should there be, in a long line of pipe, merely three or four curves of considerable radius, the flow would not be affected to any appreciable extent.

In preparing these tables we have used the "Kutter" formula, and a changeable value of "n." The diagram on the opposite page shows the various values of " $n$ " for all pipes from 2 inches up to 168 inches in diameter. It will be observed that the coefficient 0.011 is used for the larger diameters and that this valuation is slightly decreased for the smaller diameters. Many engineers calculate the flow of water in wood pipe with the valuation of " $n$ " $=0.010$. We believe that the valuation which we have given is safe and for reasonably straight pipes can be used without hesitancy.

We present a few examples of the use of this table which will readily explain how the size of pipe can be ascertained to deliver certain quantities of water, or how with the size given the frictional loss can be determined; in fact, the intelligent use of these tables can be made to do away entirely with the long tiresome calculations that are beyond the reach of the layman and are a tedious and complicated piece of work for the practicing engineer.

You wlll note that the first column represents the loss of head due to friction in 1,000 feet of pipe when discharging a given quantity of water. This frictional head can be applied to any length of pipe by multiplying by the number of thousand feet and fraction thereof, the result being the total frictional
loss in the entire pipe. The second column shows the mean velocity in feet per second, an item which is rarely considered by the layman. The third column is the discharge of the pipe in cubic feet per second. The fourth gives the discharge in gallons per minute and the fifth gives the discharge in miner's inches. The miner's inch used herein is equivalent to onefiftieth of a cubic foot per second.

In the last column is given the combined entrance and velocity heads. This figure represents the head of water which should stand over the top of the pipe at the intake in order to give the body of water in the pipe the velocity, and consequently, the discharge required. This item can be reduced nearly one-third provided that the intake end of the pipe is enlarged so as to eliminate the entrance friction. (See definition of Entrance Head.)

## EXAMPLES

1. Pipe to be used as an Inverted Syphon.

$$
\text { Given }\left\{\begin{array}{l}
\text { Size of pipe ...... } 60 \text { inches. } \\
\text { Length of pipe. . } 2200 \text { feet. } \\
\text { Discharge...... } 286 \text { cubic feet per second. } .
\end{array}\right.
$$

## Required-Total Head.

Turning to the table showing a diameter of $60^{\prime \prime}$ we find opposite the discharge of 286 cubic feet per second, that 8 feet of head is required for friction in each 1000 feet of pipe. The friction in the entire line is therefore found by $3.2 \times 8=25.6$ feet. Glancing across the same line from which we obtained the friction head, we find that 4.9 feet is required for velocity and entrance head. This added to 25.6 equals 30.5 feet, which is the Total Head required to discharge the given quantity of water.

Should occasion occur in which the exact discharge required is not found in the table, the friction head as well as the velocity and entrance heads can be determined, sufficiently close, by comparison with adjoining discharges and heads either by the eye or by simple proportion.

Should the quantity of water given be stated in gallons per minute or in miner's inches, the calculation would be effected in the same manner.
2. Pipe to be used as an Inverted Syphon.

|  | Length |
| :---: | :---: |
| Given | Discharge.................... 92 sec. feet. |
|  | --Size. |

As part of this Total Head will be taken up as velocity and entrance head, until we know the exact velocity, we can obtain only an approximate result. We therefore proceed to divide the Total Head by the number of thousands of feet of length: 36.2 divided by 4.8 equals 7.5 plus. Now let us assume that the .5 feet will be devoted to velocity and entrance head and the $\mathbf{7}$ feet to the friction head in 1000 feet of pipe. Referring to the table, and after examining several pages we find that under a diameter of 40 inches and opposite 7 feet is the required discharge, namely 92 sec. feet. We now multiply for the exact friction head: $7 \times 4.8$ equals 33.6 feet. To this add 2.6 for velocity and entrance head, giving a total of 36.2 feet. 40 inches is therefore the diameter required. In this example, it is sometimes necessary to make several trials before the correct result is obtained.
3. Pipe to be used as an Inverted Syphon.

Required-Discharge.
Divide 22.16 by 4.26 equals 5 plus. Assuming the friction head to be 5 feet, the total friction head will be 5 multiplied by 4.26 equals 21.30 . To this add velocity and entrance head .86 feet equals a total head of 22.16 feet. From the table opposite a friction head of 5 feet per 1000 it is found that the discharge is 13.3 sec . feet, the answer sought.
4. A pipe supplying water for a Power Plant.

The'size of pipe, the discharge and the friction, velocity and entrance heads may be determined as shown above but it must not be forgotten that the dynamic head is the important factor to be considered. From this alone power is developed. An increase in pipe diameter means less friction head and more dynamic head and consequently an increase in the number of horse power developed.

The economic size of pipe to employ should be given the careful study of a capable engineer.
5. A pipe used as a Pumping Line.

In pumping from a source of supply to a reservoir or ditch the water may be assumed to be lifted straight up in the air to such a height that it will, by gravity, flow to the point of discharge. For example, a pump is required to lift 3000 gallons per minute through 3500 feet of $16^{\prime \prime}$ pipe to a reservoir having its water surface 43 feet above the pump. Referring to the table, it is found that in discharging 3000 gallons per minute through a $16^{\prime \prime}$ pipe, there is 4 feet of friction head per 1000 feet of pipe, or 4 multiplied by 3.5 equals 14 feet in the entire line. The pump will therefore be compelled to work against a pumping head of 43 feet plus 14 feet equals 57 feet.

The diameter of pipe selected is governed largely by the cost of pumping and the experienced engineer should be called upon for an economic consideration of the subject.

When in the market for anything in the line of PIPE or TANKS, place your order with us.

Water in WOOD PIPE is warmer in winter and cooler in summer than in metal pipe.

DIAMETER-108 INCHES

WOOD PIPE is not affected by acids and is the ideal pipe to use for transmitting mineralized water.

## DIAMETER-8 INCHES

## INDEX

Page
A Word to Engineers ..... 8
Definitions of Hydraulic Terms. ..... 11
Hydraulic Data ..... 24
Information Required with Inquiries:
For Machine Banded Pipe ..... 5
For Continuous Stave Pipe ..... 5
Our Specialties. ..... 7
Ten Reasons for Using Wood Pipe ..... 6
TABLES
Circles, Formulae ..... 18
Equivalents:
Electrical Units ..... 15
Inches and Fractions-Decimals of a Foot. ..... 20
Inches and Fractions-Decimals of an Inch. ..... 21
Cubic Feet per Second-U. S. Gallons. ..... 22
Cubic Feet per Second-Cubic Feet. ..... 23
Effective Fire Streams ..... 25
Flow of Water:
In Open Channels ..... 32
In Pipes. ..... 37
Pipes:
Relative Capacity of ..... 26
Contents, per Foot ..... 34
Pressure of Water. ..... 30
Specific Gravities ..... 15
Tanks, Capacity of ..... 28
Triangles, Solutions of:
Right ..... 16
Oblique ..... 17
Weir Measurements. ..... 27
ILLUSTRATIONS
Machine Banded Pipe ..... 2
Tank and Tower ..... 19
Continuous Stave Pipe. ..... 35
Diagram of Kutters " $n$ " ..... 36
Cut illustrating Definitions. ..... 10
Continuous Stave Pipe Pumping Line. ..... 90
